Graphs

CS16: Introduction to Data Structures & Algorithms
Spring 2018
Outline

- What is a Graph
- Terminology
- Properties
- Graph Types
- Representations
- Performance
- BFS/DFS
- Applications
What is a Graph

- A graph is defined by
  - a set of vertices \( V \)
  - a set of edges \( E \)
- Vertices and edges can both store data
- Example
  - vertices represent airports & stores airport code
  - edges represent routes & stores distance
Terminology

- Endpoints or end vertices of an edge
  - \(U\) and \(V\) are endpoints of edge \(a\)
- Incident edges of a vertex
  - \(a, b, d\) are incident to \(V\)
- Adjacent vertices
  - \(U\) and \(V\) are adjacent
- Degree of a vertex
  - \(X\) has degree of 5
- Parallel (multiple) edges
  - \(h, i\) are parallel edges
- Self-loops
  - \(j\) is a self-looped edge
Terminology

- A path is a sequence of alternating vertices and edges
  - begins and ends with a vertex
  - each edge is preceded and followed by its endpoints
- Simple path
  - path such that all its vertices and edges are visited at most once
- Examples
  - $P_1 = V \rightarrow_b X \rightarrow_h Z$ is a simple path
  - $P_2 = U \rightarrow_c W \rightarrow_e X \rightarrow_g Y \rightarrow_f W \rightarrow_d V$ is not a simple path, but is still a path
Applications

- Flight networks
- Road networks & GPS
- The Web
  - pages are vertices
  - links are edges
- The Internet
  - routers and devices are vertices
  - network connections are edges
- Facebook
  - profiles are vertices
  - friendships are edges
Graph Properties

- A graph $G' = (V', E')$ is a **subgraph** of $G = (V, E)$ if $V' \subseteq V$ and $E' \subseteq E$.

- A graph is **connected** if there exists a path from each vertex to every other vertex.

- A path is a **cycle** if it starts and ends at the same vertex.

- A graph is **acyclic** if it has no cycles.
Graph Properties

- **A spanning tree** of $G$ is a subgraph with
  - all of $G$’s vertices in a single tree
  - and enough edges to connect each vertex w/o cycles

$G$

Spanning tree of $G$

No cycles!

Graph Properties

- A **spanning forest** is
  - a subgraph that consists of a spanning tree in each connected component of graph
- Spanning forests never contain cycles
  - this might not be the “best” or shortest path to each node

HNL — SFO — LAX

ORD — DFW — LGA — MIA — PVD

12
Graph Properties

- \( G \) is a tree if and only if it satisfies any of these conditions
  - \( G \) has \(|V| - 1\) edges and no cycles
  - \( G \) has \(|V| - 1\) edges and is connected
  - \( G \) is connected, but removing any edge disconnects it
  - \( G \) is acyclic, but adding any edges creates a cycle
  - Exactly one simple path connects each pair of vertices in \( G \)
Graph Proof 1

- Prove that
  - the sum of the degrees of all vertices of some graph $G$...
  - ...is twice the number of edges of $G$
- Let $V = \{v_1, v_2, \ldots, v_p\}$, where $p$ is the number of vertices
- The total sum of degrees $D$ is such that
  - $D = \deg(v_1) + \deg(v_2) + \ldots + \deg(v_p)$
- But each edge is counted twice in $D$
  - one for each of the two vertices incident to the edge
- So $D = 2|E|$, where $|E|$ is the number of edges.
Graph Proof 2

- Prove using induction that if \( G \) is connected then
  - \(|E| \geq |V| - 1\)
  - or \(|E| \geq n - 1\), where \( n = |V| \) is number of vertices
- Base case \( n=1 \)
  - If graph has one vertex then it will have 0 edges so \( 0 \geq 1 - 1 \)
- Inductive hypothesis
  - If graph has \( n=k \) vertices then \(|E| \geq k-1\)
- Inductive step
  - Let \( G \) be any connected graph with \( n=k+1 \) vertices
  - We must show that \(|E| \geq k\)
Graph Proof 2

- Inductive step
  - Let $G$ be any connected graph with $n = k + 1$ vertices
  - We must show that $|E| \geq k$

- Let $u$ be the vertex of minimum degree in $G$
  - $\deg(u) \geq 1$ since $G$ is connected

- If $\deg(u) = 1$
  - Let $G'$ be $G$ without $u$ and its 1 incident edge
  - $G'$ has $k$ vertices because we removed 1 vertex from $G$
  - $G'$ is still connected because we only removed a leaf
  - So by inductive hypothesis, $G'$ has at least $k - 1$ edges
  - which means that $G$ has at least $k$ edges
Graph Proof 2

- If \( \deg(u) \geq 2 \)
  - Every vertex has at least two incident edges
  - So the total degree \( D \) of the graph is \( D \geq 2(k+1) \)
  - But we know from the last proof that \( D=2|E| \)
    - so \( 2|E| \geq 2(k+1) \Rightarrow |E| \geq k+1 \Rightarrow |E| \geq k \)
- We showed it is true for \( n=1 \) (base case)...
  - ...and for \( n=k+1 \) assuming it is true for \( n=k \)...
  - ...so true for all \( n \geq 1 \)
Edge Types

- Undirected edge
  - undirected pair of vertices \((u,v)\)
  - for example a flight route

- Directed edge
  - ordered pair of vertices \((u,v)\)
  - first vertex \(u\) is the origin
  - second vertex \(v\) is the destination
  - for example a flight
Graph Types: Undirected Graph

- Undirected graph
  - all edges are undirected
Graph Types: Directed Graph

- Directed graph
  - all edges are directed
Directed Acyclic Graph (DAG)

means ‘is a prerequisite for’

We’ll talk much more about DAGs in future lectures…

Acyclic = without cycles
Graph Representations

- Vertices usually stored in a List or Set
- 3 common ways of representing which vertices are adjacent
  - Edge list (or set)
  - Adjacency lists (or sets)
  - Adjacency matrix
Edge List

- Represents adjacencies as a list of pairs
- Each element of list is a single edge \((a, b)\)
- Since order of list doesn’t matter
  - can use hashset to improve runtime of adjacency testing

\[
[(1,1), (1, 2), (1, 5), (2, 3), (2, 5), (3, 4), (4, 5), (4, 6)]
\]
Adjacency Lists

- Each vertex has an associated list with its neighbors
- Since order of these lists doesn’t matter
  - can be hashsets instead to make adjacency testing faster
Using Hashsets

- Recall that testing membership in hashset is $O(1)$
- Edge List represented as a hashset
  - $A = \{(1,1),(1,2),(1,5),(2,3),(2,5),(3,4),(4,5),(4,6)\}$
  - $A\.contains((4,5))$ is $O(1)$
- Adjacency List “lists” represented as hashsets
  - $B = \{\{1,2,5\},\{1,3,5\},\{2,4\},\{3,5,6\},\{1,2,4\},\{4\}\}$
  - $B[2]\.contains(5)$ is $O(1)$
- Could also be implemented as hash table of hashsets!
  - use hash table to find appropriate hashset then test hashset
Adjacency Matrix

- Matrix with \( n \) rows and \( n \) columns
  - \( n \) is number of vertices
  - If \( u \) is adjacent to \( v \) then \( M[u,v] = T \)
  - If \( u \) is not adjacent to \( v \) then \( M[u,v] = F \)
  - If graph is undirected then \( M[u,v] = M[v,u] \)
Adjacency Matrix

</tr>
</tbody>
</table>
Adjacency Matrix

- Initialize matrix to predicted size of our graph
  - we can always expand later
- When vertex is added to graph
  - reserve a row and column of matrix for that vertex
- When vertex is removed
  - set its row and column to false
- Since we can’t remove rows/columns from arrays
  - keep separate collection of vertices that are actually present in graph
Graph ADT

- Vertices and edges store values
  - Ex: edge weights
- Accessor methods
  - `vertices()`
  - `edges()`
  - `incidentEdges(vertex)`
  - `areAdjacent(v1, v2)`
  - `endVertices(edge)`
  - `opposite(vertex, edge)`
- Update methods
  - `insertVertex(value)`
  - `insertEdge(v1, v2)`
    - sometimes this function also takes a value
    - so `insertEdge(v1, v2, val)`
  - `removeVertex(vertex)`
  - `removeEdge(edge)`

BFT and DFT

- Remember BFT and DFT on trees?
- We can also do them on graphs
  - a tree is just a special kind of graph
  - often used to find certain values in graphs
BFT/DFT on Graphs

BFT/DFT on Graphs
Breadth First Traversal: Tree vs. Graph

function **treeBFT**(root):

// Input: Root node of tree
// Output: Nothing
Q = new Queue()
Q.enqueue(root)
while Q is not empty:
    node = Q.dequeue()
doSomething(node)
enqueue node’s children

doSOMETHING() could
print, add to list, decorate
node etc…

function **graphBFT**(start):

// Input: start vertex
// Output: Nothing
Q = new Queue()
start.visited = true
Q.enqueue(start)
while Q is not empty:
    node = Q.dequeue()
doSomething(node)
for neighbor in adj nodes:
    if not neighbor.visited:
        neighbor.visited = true
        Q.enqueue(neighbor)

Mark nodes as visited otherwise you will loop forever!
Depth First Traversal

- To do DFT on graph, replace queue with stack
- Can also be done recursively

```javascript
function recursiveDFT(node):
    // Input: start node
    // Output: Nothing
    node.visited = true
    for neighbor in node’s adjacent vertices:
        if not neighbor.visited:
            recursiveDFT(neighbor)
```
Applications: Flight Paths Exist

- Given undirected graph with airports & flights
  - is it possible to fly from one airport to another?
- Strategy
  - use breadth first search starting at first node
  - and determine if ending airport is ever visited
Applications: Flight Paths Exist

- Is there a flight from SFO to PVD?
Applications: Flight Paths Exist

- Is there flight from SFO to PVD?
Applications: Flight Paths Exist

- Is there flight from SFO to PVD?
Applications: Flight Paths Exist

- Is there flight from SFO to PVD?

- Yes! but how do we do it with code?
Flight Paths Exist Pseudo-Code

function $\text{pathExists}(\text{from}, \text{to})$:
   
   // Input: from: vertex, to: vertex  
   // Output: true if path exists, false otherwise  
   
   $Q = \text{new Queue()}$
   $\text{from.visited} = \text{true}$
   $Q.\text{enqueue}(\text{from})$
   
   while $Q$ is not empty:
      
      $\text{airport} = Q.\text{dequeue}()$
      
      if $\text{airport} == \text{to}$:
         return true
      
      for $\text{neighbor}$ in $\text{airport}$’s adjacent nodes:
         
         if not $\text{neighbor.visited}$:
            $\text{neighbor.visited} = \text{true}$
            $Q.\text{enqueue}(\text{neighbor})$

   return false
Applications: Flight Layovers

- Given undirected graph with airports & flights
  - decorate vertices w/ least number of stops from a given source
  - if no way to get to an airport decorate w/ $\infty$

- Strategy
  - decorate each node w/ initial ‘stop value’ of $\infty$
  - use breadth first search to decorate each node…
  - …w/ ‘stop value’ of one greater than its previous value
function **numStops**(G, source):

// Input: G: graph, source: vertex
// Output: Nothing
// Purpose: decorate each vertex with the lowest number of layovers from source.

for every node in G:
    node.stops = infinity

Q = new Queue()
source.stops = 0
source.visited = true
Q.enqueue(source)

while Q is not empty:
    airport = Q.dequeue()
    for neighbor in airport’s adjacent nodes:
        if not neighbor.visited:
            neighbor.visited = true
            neighbor.stops = airport.stops + 1
            Q.enqueue(neighbor)
