# CSCI-1680 Network Layer: Wrapup

Rodrigo Fonseca

### Administrivia

### Homework 2 is due tomorrow

- So we can post solutions before the midterm!

### Exam on Tuesday

- All content up to today
- Questions similar to the homework
- Book has some exercises, samples on the course web page (from previous years)

# Today: IP Wrap-up

- IP Service models
  - Unicast, Broadcast, Anycast, Multicast
- **IPv6** 
  - Tunnels

### **Different IP Service Models**

- Broadcast: send a packet to *all* nodes in some subnet. "One to all"
  - 255.255.255.255 : all hosts within a subnet, *never* forwarded by a router
  - "All ones host part": broadcast address
    - Host address | (255.255.255.255 & ~subnet mask)
    - E.g.: 128.148.32.143 mask 255.255.255.128
    - $\sim$  mask = 0.0.0.127 => Bcast = 128.148.32.255
- Example use: DHCP
- Not present in IPv6
  - Use multicast to link local all nodes group

## **Anycast**

- Multiple hosts may share the same IP address
- "One to one of many" routing
- Example uses: load balancing, nearby servers
  - DNS Root Servers (e.g. f.root-servers.net)
  - Google Public DNS (8.8.8.8)
  - IPv6 6-to-4 Gateway (192.88.99.1)

## **Anycast Implementation**

- Anycast addresses are /32s
- At the BGP level
  - Multiple ASs can advertise the same prefixes
  - Normal BGP rules choose one route
- At the Router level
  - Router can have multiple entries for the same prefix
  - Can choose among many
- Each packet can go to a different server
  - Best for services that are fine with that (connectionless, stateless)

## **Multicast**

- Send messages to many nodes: "one to many"
- Why do that?
  - Snowcast, Internet Radio, IPTV
  - Stock quote information
  - Multi-way chat / video conferencing
  - Multi-player games
- What's wrong with sending data to each recipient?
  - Link stress
  - Have to know address of all destinations

### **Multicast Service Model**

- Receivers join a multicast group G
- Senders send packets to address G
- Network routes and delivers packets to all members of G
- Multicast addresses: class D (start 1110) 224.x.x.x to 229.x.x.x
  - 28 bits left for group address

### LAN Multicast

- Easy on a shared medium
- Ethernet multicast address range:
  - 01:00:5E:00:00:00 to 01:00:5E:7f:ff:ff
- Set low 23 bits of Ethernet address to low bits of IP address
  - (Small problem: 28-bit group address -> 23 bits)

How about on the Internet?

### **Use Distribution Trees**

### • Source-specific trees:

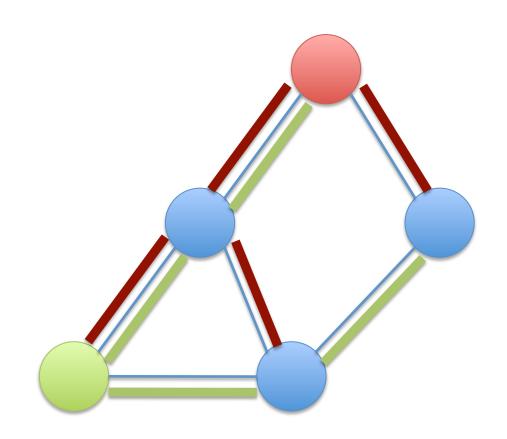

- Spanning tree over recipients, rooted at each source
- Best for each source

### • Shared trees:

- Single spanning tree among all sources and recipients
- Hard to find one shared tree that's best for many senders
- State in routers much larger for source-specific

## **Source vs Shared Trees**

## **Building the Tree: Host to Router**

- Nodes tell their local routers about groups they want to join
  - IGMP, Internet Group Management Protocol (IPv4)
  - MLD, Multicast Listener Discovery (IPv6)
- Router periodically polls LAN to determine memberships
  - Hosts are not required to leave, can stop responding

## Building the Tree across networks

- Routers maintain multicast routing tables
  - Multicast address -> set of interfaces, or
  - <Source, Multicast address> -> set of interfaces
- Critical: only include interfaces where there are downstream recipients

### **Practical Considerations**

- Multicast protocols end up being quite complex
- Introduce a lot of router state
- Turned off on most routers
- Mostly used within domains
  - In the department: Ganglia monitoring infrastructure
  - IPTV on campus
- Alternative: do multicast in higher layers

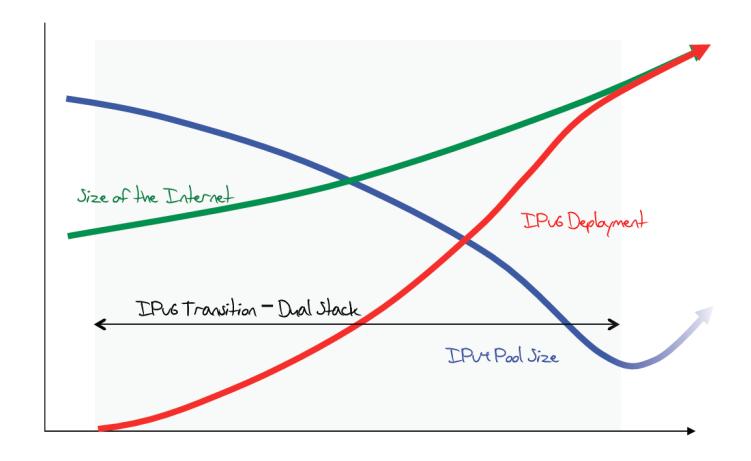

### IPv6

- Main motivation: IPv4 address exhaustion
- Initial idea: larger address space
- Need new packet format:
  - REALLY expensive to upgrade all infrastructure!
  - While at it, why don't we fix a bunch of things in IPv4?
- Work started in 1994, basic protocol published in 1998

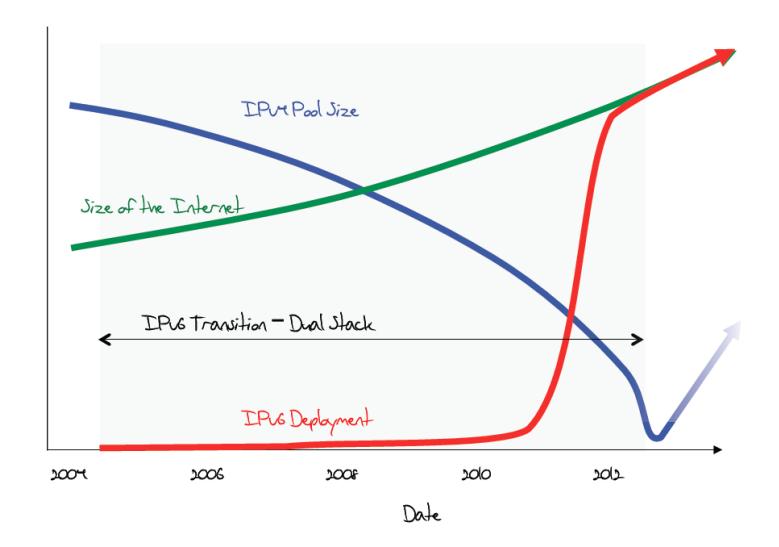

## The original expected plan

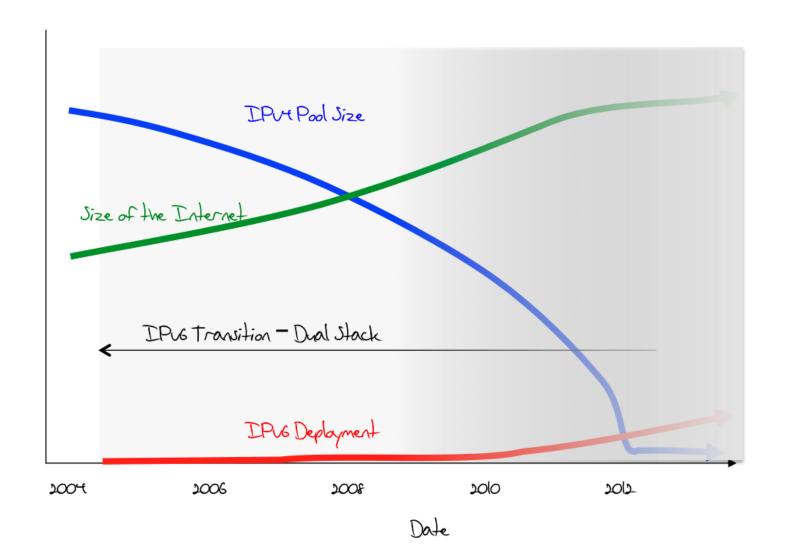

# The plan in 2011

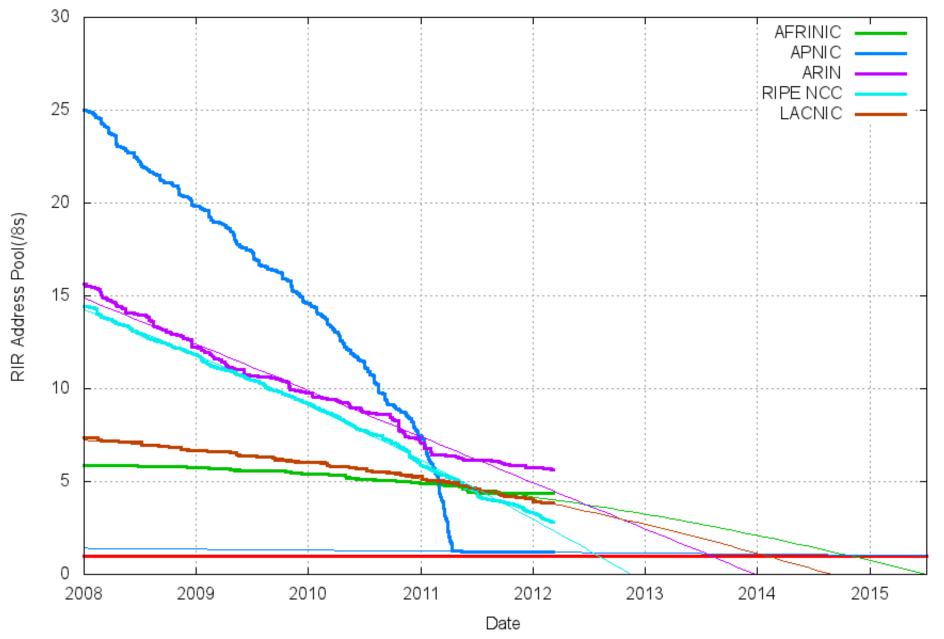

# What is really happening

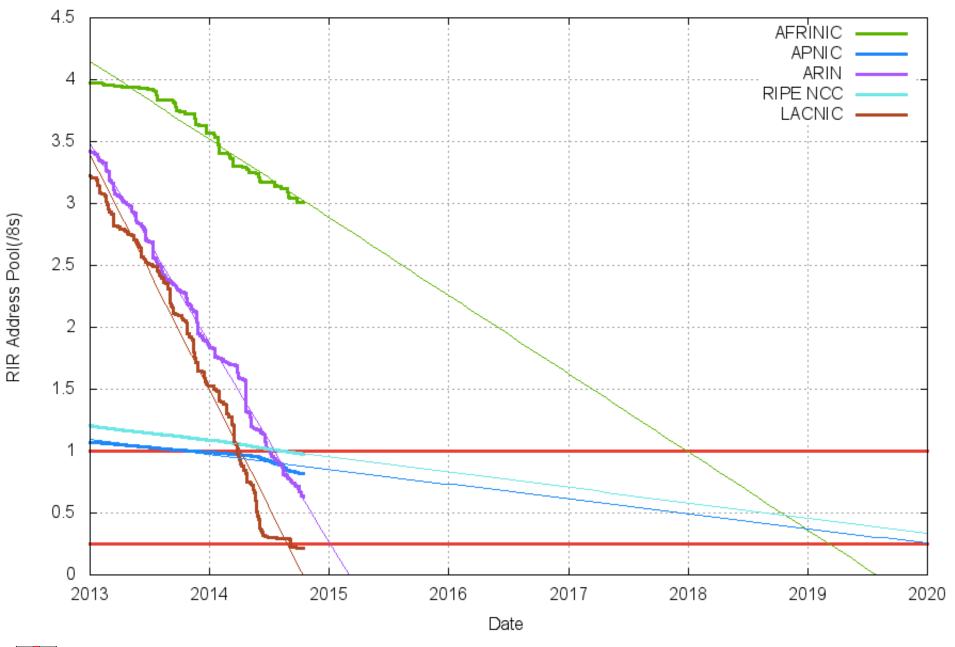

#### RIR IPv4 Address Run-Down Model

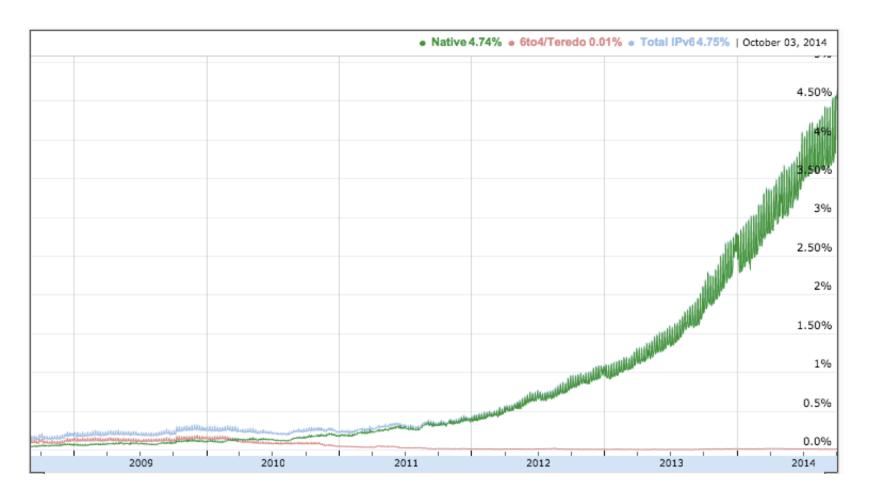

Source: potaroo.net/tools/ipv4

# **Current Adoption (as seen by Google)**

## **IPv6 Key Features**

- 128-bit addresses
  - Autoconfiguration
- Simplifies basic packet format through extension headers
  - 40-byte base header (fixed)
  - Make less common fields optional
- Security and Authentication

## **IPv6 Address Representation**

• Groups of 16 bits in hex notation 47cd:1244:3422:0000:0000:fef4:43ea:0001

- Two rules:
  - Leading 0's in each 16-bit group can be omitted
    47cd:1244:3422:0:0:fef4:43ea:1
  - One contiguous group of 0's can be compacted47cd:1244:3422::fef4:43ea:1

## **IPv6 Addresses**

# • Break 128 bits into 64-bit network and 64-bit interface

 Makes autoconfiguration easy: interface part can be derived from Ethernet address, for example

## Types of addresses

- All 0's: unspecified
- 000...1: loopback
- ff/8: multicast
- fe8/10: link local unicast
- fec/10: site local unicast
- All else: global unicast

### IPv6 Header

Ver Class **Flow** Next Hdr. | Hop limit Length Source (16 octets, 128 bits) **Destination** (16 octets, 128 bits)

### **IPv6 Header Fields**

- Version: 4 bits, 6
- Class: 8 bits, like TOS in IPv4
- Flow: 20 bits, identifies a *flow*
- Length: 16 bits, datagram length
- Next Header, 8 bits: ...
- Hop Limit: 8 bits, like TTL in IPv4
- Addresses: 128 bits
- What's missing?
  - No options, no fragmentation flags, no checksum

# Design Philosophy

### Simplify handling

- New option mechanism (fixed size header)
- No more header length field

## Do less work at the network (why?)

- No fragmentation
- No checksum

### General flow label

- No semantics specified
- Allows for more flexibility

## Still no accountability

## Interoperability

### RFC 4038

- Every IPv4 address has an associated IPv6 address (mapped)
- Networking stack translates appropriately depending on other end
- Simply prefix 32-bit IPv4 address with 80 bits of 0 and 16 bits of 1:
- E.g., ::FFFF:128.148.32.2

### Two IPv6 endpoints must have IPv6 stacks

### Transit network:

$$- v4 - v4 - v4 : \checkmark$$

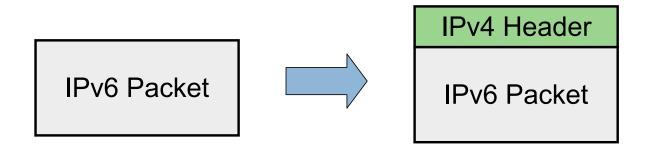

$$- v4 - v6 - v4 : \checkmark$$

$$- v6 - v4 - v6 :$$

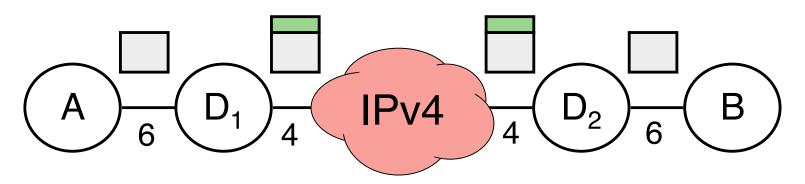

# **IP Tunneling**

- Encapsulate an IP packet inside another IP packet
- Makes an end-to-end path look like a single IP hop

## IPv6 in IPv4 Tunneling

### Key issues: configuring the tunnels

- Determining addresses
- Determining routes
- Deploying relays to encapsulate/forward/decapsulate

### Several proposals, not very successful

- 6to4, Teredo, ISATAP
- E.g., 6to4
  - Deterministic address generation
  - Anycast 192.88.99.1 to find gateway into IPv6 network
  - Drawbacks: voluntary relays, requires public endpoint address

# Other uses for tunneling

- Virtual Private Networks
- Use case: access CS network from the outside
  - Set up an encrypted TCP connection between your computer and Brown's OpenVPN server
  - Configure routes to Brown's internal addresses to go through this connection
- Can connect two remote sites securely

### **Extension Headers**

- Two types: hop-by-hop and end-to-end
- Both have a next header byte
- Last next header also denotes transport protocol
- Destination header: intended for IP endpoint
  - Fragment header
  - Routing header (loose source routing)
- Hop-by-hop headers: processed at each hop
  - Jumbogram: packet is up to 2<sup>32</sup> bytes long!

## **Example Next Header Values**

- 0: Hop by hop header
- 1: ICMPv4
- 4: IPv4
- 6:TCP
- 17: UDP
- 41: IPv6
- 43: Routing Header
- 44: Fragmentation Header
- 58: ICMPv6

## Fragmentation and MTU

- Fragmentation is supported only on end hosts!
- Hosts should do MTU discovery
- Routers will not fragment: just send ICMP saying packet was too big
- Minimum MTU is 1280-bytes
  - If some link layer has smaller MTU, must interpose fragmentation reassembly underneath

### **Current State**

- IPv6 Deployment has been slow
- Most end hosts have dual stacks today (Windows, Mac OSX, Linux, \*BSD, Solaris)
- 2008 Google study:
  - Less than 1% of traffic globally
- Requires all parties to work!
  - Servers, Clients, DNS, ISPs, all routers
- IPv4 and IPv6 will coexist for a long time

## Next time: Midterm

- After that, transport layer and above!
  - UDP, TCP, Congestion Control
  - Application protocols
  - **—** ...
