

CSCI-1680

RPC and Data Representation

John Jannotti

Original Slides from Rodrigo Fonseca

Today

- **Defining Protocols**
 - RPC
 - IDL

Problem

- **Two programs want to communicate: must define the protocol**
 - We have seen many of these, across all layers
 - E.g., Snowcast packet formats, protocol headers
- **Key Problems**
 - Semantics of the communication
 - APIs, how to cope with failure
 - Data Representation
 - Scope: should the scheme work across
 - Architectures
 - Languages
 - Compilers...?

RPC – Remote Procedure Call

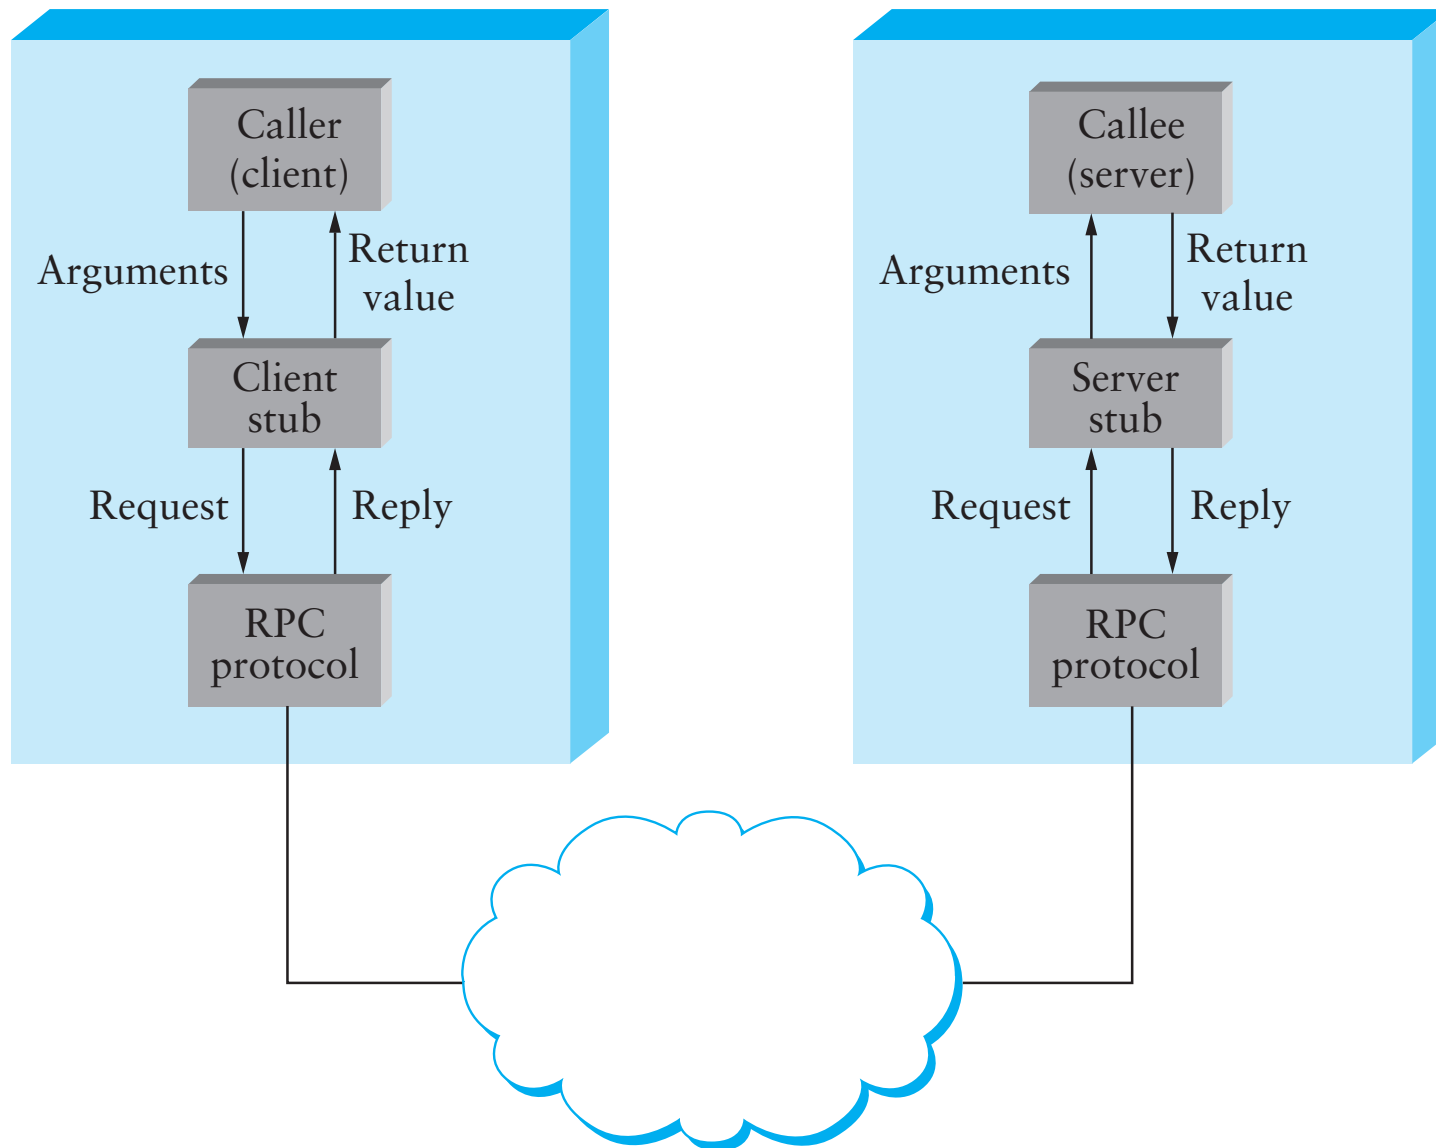

- **Procedure calls are a well understood mechanism**
 - Transfer control and data on a single computer
- **Idea: make distributed programming look the same**
 - Have servers export interfaces that are accessible through local APIs
 - Perform the illusion behind the scenes
- **Two Major Components**
 - Protocol to manage messages sent between client and server
 - Language and compiler support
 - Packing, unpacking, calling function, returning value

Stub Functions

- **Local stub functions at client and server give appearance of a local function call**
- **client stub**
 - marshalls parameters -> sends to server -> waits (some RPC-like mechanisms offer asynchrony)
 - unmarshalls results -> returns to client
- **server stub**
 - creates socket/ports and accepts connections
 - receives message from client stub -> unmarshalls parameters -> calls server function
 - marshalls results -> sends results to client stub

Can we maintain the same semantics?

- **Mostly...**
- **Why not?**
 - New failure modes: nodes, network
- **Possible outcomes of failure**
 - Procedure did not execute
 - Procedure executed once
 - Procedure executed multiple times
 - Procedure partially executed
- **Desired: at-most-once semantics**

Implementing at-most-once semantics

- **Problem: request message lost**
 - Client must retransmit requests when it gets no reply
- **Problem: reply message lost**
 - Client may retransmit previously executed request
 - OK if operation is *idempotent*
 - Server must keep “replay cache” to reply to already executed requests
- **Problem: server takes too long executing**
 - Client will retransmit request already in progress
 - Server must recognize duplicate – could reply “in progress”
- **Solution: Send messages over TCP?**

Server Crashes

- **Problem: server crashes and reply lost**
 - Make replay cache persistent – slow, odd interface
 - Hope reboot takes long enough for all clients to fail
- **Problem: server crashes during execution**
 - Log enough to restart partial execution – slow and hard
 - Hope reboot takes long enough for all clients to fail
- **Can use “cookies” to inform clients of crashes**
 - Server gives client cookie, which is $f(\text{time of boot})$
 - Client includes cookie with RPC
 - After server crash, server will reject invalid cookie

RPC Components

- **Stub Compiler**
 - Creates stub methods
 - Creates functions for marshalling and unmarshalling
- **Dispatcher**
 - Demultiplexes programs running on a machine
 - Calls the stub server function
- **Protocol**
 - At-most-once semantics (or not)
 - Reliability, replay caching, version matching
 - Fragmentation, Framing (depending on underlying protocols)

Examples of RPC Systems

- **SunRPC (now ONC RPC)**
 - The first popular system
 - Used by NFS
 - Not popular for the wide area (security, convenience)
- **Java RMI**
 - Popular with Java
 - Only works among JVMs
- **DCE**
 - Used in ActiveX and DCOM, CORBA
 - Stronger semantics than SunRPC, much more complex

...even more examples

- **XML-RPC, SOAP**
- **Json-RPC**
- **Apache Thrift**

Presentation Formatting

- **How to represent data?**
- **Several questions:**
 - Which data types do you want to support?
 - Base types, Flat types, Complex types
 - How to encode data into the wire
 - How to decode the data?
 - Self-describing (tags)
 - Implicit description (the ends *know*)
- **Several answers:**
 - Many frameworks do these things automatically

Which data types?

- **Basic types**
 - Integers, floating point, characters
 - Some issues: endianness (ntohs, htons), character encoding, IEEE 754, unions
- **Flat types**
 - Strings, structures, arrays
 - Some issues: packing of structures, order, variable length
- **Complex types**
 - Pointers! Must flatten, or serialize data structures

Application data structure

Data Schema

- **How to parse the encoded data?**
- **Two Extremes:**
 - Self-describing data: tags
 - Additional information added to message to help in decoding
 - Examples: field name, type, length
 - Implicit: the code at both ends “knows” how to decode the message
 - *E.g.*, your Snowcast implementation
 - Interoperability depends on well defined protocol specification!
 - very difficult to change

Stub Generation

- **Many systems generate stub code from independent specification: IDL**
 - IDL – Interface Description Language
 - describes an interface in a **language neutral** way
- **Separates logical description of data from**
 - Dispatching code
 - Marshalling/unmarshalling code
 - Data wire format

Example: Sun XDR (RFC 4506)

- ***External Data Representation for SunRPC***
- **Types:** most of C types
- **No tags (except for array lengths)**
 - Code needs to know structure of message
- **Usage:**
 - Create a program description file (.x)
 - Run rpcgen program
 - Include generated .h files, use stub functions
- **Very C/C++ oriented**
 - Although encoders/decoders exist for other languages

Example: fetch and add server

- In `fadd_prot.x`:

```
struct fadd_arg {  
    string var<>;  
    int inc;  
};
```

```
union fadd_res switch (bool error) {  
case TRUE:  
    int sum;  
case FALSE:  
    string msg<>;  
};
```

RPC Program Definition

```
program FADD_PROG {  
    version FADD_VERS {  
        void FADDPROC_NULL (void) = 0;  
        fadd_res FADDPROC_FADD (fadd_arg) = 1;  
    } = 1;  
} = 300001;
```

- **Rpcgen generates marshalling/unmarshalling code, stub functions, you fill out the actual code**

XML

- **Other extreme**
- **Markup language**
 - Text based, semi-human readable
 - Heavily tagged (field names)
 - Depends on external schema for parsing
 - Hard to parse efficiently
 - Easier to extend compatibly

```
<person>  
  <name>John Doe</name>  
  <email>jdoe@example.com</email>  
</person>
```

Google Protocol Buffers

- **Defined by Google, released to the public**
 - Widely used internally and externally
 - Supports common types, service definitions
 - Natively generates C++/Java/Python code
 - Over 20 other supported by third parties
 - Not a full RPC system, only does marshalling
 - Many third party RPC implementations
 - Efficient binary encoding, readable text encoding
- **Performance**
 - 3 to 10 times smaller than XML
 - 20 to 100 times faster to process

Protocol Buffers Example

```
message Student {  
    required String name = 1;  
    required int32 credits = 2;  
}
```

(...compile with proto)

```
Student s;  
s.set_name("Jane");  
s.set_credits(20);  
fstream output("students.pb" , ios:out | ios:binary );  
s.SerializeToOstream(&output);
```

(...somebody else reading the file)

```
Student s;  
fstream input("students.pb" , ios:in | ios:binary );  
s.ParseFromIstream();
```

Binary Encoding

- **Integers: varints**
 - 7 bits out of 8 to encode integers
 - Msb: more bits to come
 - Multi-byte integers: least significant group first
- **Signed integers: zig-zag encoding, then varint**
 - 0:0, -1:1, 1:2, -2:3, 2:4, ...
 - Advantage: smaller when encoded with varint
- **General:**
 - Field number, field type (tag), value
- **Strings:**
 - Varint length, unicode representation

Apache Thrift

- **Originally developed by Facebook**
- **Used heavily internally**
- **Full RPC system**
 - Support for C++, Java, Python, PHP, Ruby, Erlang, Perl, Haskell, C#, Cocoa, Smalltalk, and Ocaml
- **Many types**
 - Base types, list, set, map, exceptions
- **Versioning support**
- **Many encodings (protocols) supported**
 - Efficient binary, json encodings

Apache Avro

- **Yet another newcomer**
- **Likely to be used for Hadoop data representation**
- **Encoding:**
 - Compact binary with schema included in file
 - Amortized self-descriptive
- **Why not just create a new encoding for Thrift?**
 - I don't know...

Conclusions

- **RPC is good way to structure many distributed programs**
 - Have to pay attention to different semantics, though!
- **Data: tradeoff between self-description, portability, and efficiency**
- **Unless you really want to bit pack your protocol, and it won't change much, use one of the IDLs**
- **Parsing code is easy to get (slightly) wrong, hard to get fast**
 - Should only do this once, for all protocols
