

The `equationarray` environment

Roland Winkler

`roland.winkler@physik.uni-regensburg.de`

January 16, 2004

Abstract

The `equationarray` combines the line numbering of the `eqnarray` and the more flexible formatting features of the `array` environment. This package requires the `array` package.

1 Introduction

Problem: The `eqnarray` environment is too restrictive because it is only prepared to accept three part equations. Some applications require more sophisticated mathematics, so three parts aren't enough. Simultaneously, we would like to have our equations numbered. If the equations aren't to be numbered, then the `array` environment suffices. (Nevertheless it is often easier to use the `equationarray*` environment than both an `equation` plus an `array` environment.) If the equations aren't to be aligned with each other, then the `equation` environment is preferred.

The following is a new version of Tony Li's `equationarray` environment modified such that it is compatible with Frank Mittelbach's `array` environment, i.e. it should be possible to use all options of the `array` environment. If you find a bug (see below!) or if you make any improvements, I'd like to hear about them.

When writing the `equationarray` environment I used the version v2.1b of the `array` environment. The original version of `equationarray` was written by Tony Li, University of Southern California, `tli@sargas.usc.edu` starting 6/15/88.

I know that my documentation of the `equationarray` environment is rather short. So if you think that it would be useful to have a better documentation please let me know.

2 Example

We give a short example for the use of `equationarray`. The text is

```
\newcolumntype{e}{@{\quad}}
\arraycolsep 0.2em
```

```

\begin{equationarray}[p{2.5em}erclecercl]
now: & - i\partial_t \psi & = & H\psi & \Rightarrow & \psi(t) = \psi(0) \exp(iEt) \\
& \psi(t) & = & \psi(0) \exp(iEt) \\
then: & - i\partial_t \psi & = & (H+E_0)\psi & \Rightarrow & \psi(t+t_0) = \psi(t_0) \exp[i(E+E_0)t]
\end{equationarray}

```

and we obtain

$$\text{now: } -i\partial_t\psi = H\psi \quad \Rightarrow \quad \psi(t) = \psi(0)\exp(iEt) \quad (1)$$

$$\text{then: } -i\partial_t\psi = (H + E_0)\psi \quad \Rightarrow \quad \psi(t + t_0) = \psi(t_0)\exp[i(E + E_0)t] \quad (2)$$

An `equationarray` behaves very much like an `array`. For example, `equationarray` takes the same tokens for defining columns, and new column types can be defined with `\newcolumn`. One can use `\multicolumn`, `\hline`, `\cline`, and `\vline`, and `equationarray` makes use of `\arraycolsep`, `\extracolsep`, and `\extrarowheight`.¹ In an `equationarray` all these things have the same meaning like in an `array`. The main difference is that by default each entry of an `equationarray` is displayed with `\displaystyle` whereas `array` uses `\textstyle`. One can avoid page breaks between two lines by using the star-version `*`. There is also the star-version `equationarray*` which has usually no line numbers. But if for a particular line you still want a line number, you can use `\yesnumber`. (I find this easier than many lines with `\nonumber`.) With the options `[l]` or `[r]` the `equationarray` will appear flush-left or flushright, with the options `[c]` the `equationarray` will be centered, e.g. `\begin{equationarray}[l]{rc1l1}`. The default will be centering without the `fleqn` option and left-justified, indented by `\mathindent` with the `fleqn` option. Thanks to Piet van Oostrum <piet@cs.ruu.nl> who added the code which is necessary for the `fleqn` option.

3 Bugs

The `equationarray` has a slightly modified version of `\multicolumn` because we must count the `\spanned` columns. Thus if you have `\multicolumn` within an `array` within the `equationarray` environment, then you might run into difficulties if you have a line with less `&`'s than columns defined in the preamble.

Thus you can either fill up the end of a half empty line with extra `&`'s or you can put the original definition of `\multicolumn` within the definition of the `array` command.

¹Some people don't like the large spacing between the columns of the standard `eqnarray`. Don't be surprised that `equationarray` seems to have the same "bug". You just have to change the value of `\arraycolsep`, see the example above.

4 The code

```

\typeout{equationarray \fileversion\space<\filedate>}
\typeout{English documentation\space\space<\docdate>}

equationarray can't do anything if one doesn't provide the array package.
\RequirePackage{array}

Process the fleqn option.
\def\eqnarr@left{\@centering}
\let\eqnarr@opts\relax
\DeclareOption{fleqn}{
  \def\eqnarr@left{\mathindent}
  \def\eqnarr@opts{\displaywidth\linewidth
    \advance\displaywidth-\mathindent} }
\ProcessOptions

```

`\equationarray`

```

\def\equationarray{%
  \col@sep\arraycolsep
  \def\d@llarbegin{${\displaystyle}}%
  \def\d@llarend{${}}%
  \stepcounter{equation}%
  \let\@currentlabel=\theequation
  \set@eqnsw \global\@eqcnt\z@ \global\@eqargcnt\z@
  \let\@classz\@eqnclassz

```

We need an extended definition of `\multicolumn` which increases the counter `\@eqcnt` according to the number of columns covered by `\multicolumn`.

```

\def\multicolumn##1##2##3{\@eqnmulticolumn{##1}{##2}{##3}%
  \global\advance\@eqcnt##1
  \global\advance\@eqcnt\m@ne}%
\def\@halignto{to\displaywidth}%
\ifnextchar[{\@equationarray}{\@equationarray[.]}}

```

`\@eqnmulticolumn` `\@eqnmulticolumn` equals the original version of `\multicolumn`.
`\let\@eqnmulticolumn=\multicolumn`

`\nonumber, \yesnumber` Note, that `\nonumber` is already defined in standard `latex.tex`

```

% \def\nonumber{\global\@eqnswfalse}
\def\yesnumber{\global\@eqnswtrue}
\let\set@eqnsw=\yesnumber

```

`\@amper` We need a macro for `&` that expands at the right time.

```
\def\@amper{&}
```

`\@eqargcnt` We must count the number of columns defined in the preamble so that we can fill every line with exactly `\@eqargcnt` copies of `&` before we insert the equation number.

```
\newcount\@eqargcnt % counts number of columns
```

`\@equationarray` The definition of `\@equationarray` follows the T_EXbook, Exercise 22.9

```

\def\@equationarray[#1]#2{%
  \eqnarr@opts
  \@tempdima \ht \strutbox
  \advance \@tempdima by\extrarowheight
  \setbox\@arstrutbox=\hbox{\vrule
    \@height\arraystretch \@tempdima
    \@depth\arraystretch \dp \strutbox
    \@width\z@}%
  \gdef\advance@eqargcnt{\global\advance\@eqargcnt\@ne}%
  \begingroup
  \mkpream{#2}%
  \xdef\@preamble{%
    \if #1\tabskip\z@ \else\if #1r\tabskip\@centering
      \else\if #1c\tabskip\@centering
        \else\tabskip\eqnarr@left \fi\fi\fi

    \halign \@halignto
    \bgroup \tabskip\z@ \@arstrut \@preamble
    \if #1l\tabskip\@centering \else\if #1r\tabskip\z@
      \else\tabskip\@centering \fi\fi

```

Here we need an extra column for the equation-number

```

  \@amper\llap{\@sharp}\tabskip\z@\cr}%
\endgroup
\gdef\advance@eqargcnt{}%
\bgroup
\let\@sharp## \let\protect\relax
\m@th \let\=\@equationcr
\let\par\@empty
$$ % $$ BRACE MATCHING HACK
\lineskip \z@
\baselineskip \z@
\@preamble}

```

`\@eqnclassz` `\@eqnclassz` does the same thing as `\@classz` except that we add `\advance@eqargcnt`

```

\def\@eqnclassz{\@classz
  \@tempcnta \count@
  \advance@eqargcnt
  \prepnext@tok
  \@addtopreamble{%
    \global\advance\@eqcnt\@ne
    \ifcase \@chnum
    \hfil \dollarbegin \insert@column \dollarend\hfil \or
    \dollarbegin \insert@column \dollarend \hfil \or
    \hfil\kern\z@ \dollarbegin \insert@column \dollarend \or
    $\vcenter
    \@startpbox{\@nextchar}\insert@column \@endpbox $\or
    \vtop \@startpbox{\@nextchar}\insert@column \@endpbox \or
    \vbox \@startpbox{\@nextchar}\insert@column \@endpbox

```

```

\fi}\prepnext@tok}

\endequationarray
\def\endequationarray{\@zequationcr
  \egroup
  \global\advance\c@equation\m@ne $$$ % $$$ BRACE MATCHING HACK
  \egroup\global\@ignoretrue
  \gdef\@preamble{}}

\@equationcr If we have \\* the command \@equationcr avoids page breaks
\def\@equationcr{${\ifnum0='}\fi\@ifstar{\global\@eqpen\@M
  \@xequationcr}{\global\@eqpen\interdisplaylinepenalty
  \@xequationcr}}

\@xequationcr
\def\@xequationcr{%
  \@ifnextchar[{\@argequationcr}{\ifnum0='{}\fi}$}%
  \@zequationcr}}

\@argequationcr
\def\@argequationcr[#1]{\ifnum0='{}\fi}$\ifdim #1>\z@
  \@xargequationcr[#1]\else
  \@yargequationcr[#1]\fi}

\@xargequationcr
\def\@xargequationcr#1{\unskip
  \@tempdima #1\advance\@tempdima \dp \@arstrutbox
  \vrule \@depth\@tempdima \@width\z@
  \@zequationcr\noalign{\penalty\@eqpen}}

\@yargequationcr
\def\@yargequationcr#1{%
  \@zequationcr\noalign{\penalty\@eqpen\vskip #1}}
  We add &\omit for those columns that will remain empty. Note that without
  \omit we already have \advance\@eqcnt\@one in the preamble.
  \def\@zequationcr{\@whilenum\@eqcnt <\@eqargcnt
    \do{\@amper\omit\global\advance\@eqcnt\@one}}%
  We add an extra alignment tab for the equationnumber
  \@amper
  \if@eqnsw\@eqnnum\stepcounter{equation}\fi
  \set@eqnsw\global\@eqcnt\z@\cr}

\equationarray* Finally we define the equationarray* environment. It does exactly the same
thing as \equationarray except that we \let the command \set@eqnsw equal
\nonumber
\@namedef{equationarray*}{%
  \let\set@eqnsw=\nonumber \equationarray}
\@namedef{endequationarray*}{\endequationarray}

```
