

Logging

{ “We therefore consider this bottleneck as the most dangerous to future scalability”

- ⌘ Canonical recovery algorithm
- ⌘ Decouples data writing from log writing

ARIES

- ⌘ Write ahead logging
- ⌘ Restoring database to pre-crash
- ⌘ Undoing uncommitted txns

3 Components

⌘ Create an additional log while undoing transactions to recover multiple crashes

Multiple Crashes

Aether

- ⌘ OLTP txns are small and frequent
- ⌘ More cores → more contention
- ⌘ Other bottlenecks disappearing

Motivation

- I/O delay
- Lock contention
- Schedule overhead
- Log buffer contention

Convolutd Drawing

Tradeoffs suck.

Speed + security rocks.

- ⌘ Critical path
- ⌘ Decouple to reduce contention
- ⌘ Commit $\neq$ return

Key Ideas

- ⌘ Critical path
- ⌘ Decouple to reduce contention
- ⌘ Commit $\neq$ return

Key Ideas

I/O Delay and Scheduling

- ⌘ Release locks on commit
- ⌘ Track dependencies
- ⌘ Abort and rollback if necessary

Early Lock Release

Client Request

Database

Commit

Client Request

Database

Commit

- ⌘ Decouples transaction commit from scheduling
- ⌘ Keeps threads busy

Flush Pipelining

⌘ Allowing other transactions to proceed speculatively + providing the threads to actually execute them rivals asynchronous commit, but SAFELY

Combining the Two

Questions?

Scalable Log Buffer

{ High core count +
high load →
bottleneck in the log
buffer

Log Buffer Bottleneck

- ⌘ To write to the log, threads
 - ⌘ Acquire space in the buffer
 - ⌘ Fill space
 - ⌘ Release buffer space for writing

The Problem

- ⌘ Group logs together to write to the buffer at once
- ⌘ Use a consolidation array as a backoff structure

Solution C

Observation

Push()

linearizable stack

Pop()

Yes!

After an equal number
of pushes and pops,
stack stays the same

Idea: Elimination Array

Push()

Pick at
random

stack

Pop()

Pick at
random

**Elimination
Array**

Push Collides With Pop

No Collision

If pushes collide
or pops collide
access stack

Elimination-Backoff Stack

- Lock-free stack + elimination array
- Access Lock-free stack,
 - If **uncontended**, apply operation
 - if **contended**, back off to elimination array and attempt elimination

- ⌘ Consolidation array combines updates rather than eliminating them
- ⌘ Group leader does all the work
- ⌘ Great in theory as well as practice

Consolidation Array

- ⌘ Buffer fill is not inherently serial
- ⌘ Must release regions in proper order

Decoupled Buffer Fill

⌘ Hybrid approach

⌘ Consolidate and fill buffer in parallel

Two > One

Quick Summary

Does it actually work?

- Left shows record size average held to 120B constant
- Right shows thread count constant (64)

Experimental Results

How good?

- Left shows record size average held to 120B constant
- Right shows thread count constant (64)

Experimental Results

- ✧ Flush pipelining + ELR is most important
- ✧ Log buffer contention become increasingly important as core-counts grow

Overall Picture

- ⌘ Delegation can prevent the problem with varying record size
- ⌘ Threads wake the next in line
- ⌘ More robust, but performance penalty in the normal case

Further Optimization

In summary...

- ⌘ Distributed logging
- ⌘ Higher level (txn + parameters)
- ⌘ Different (serial excn per thread)
- ⌘ Txns strongly ordered

H-Store WAL

- ⌘ Sharing the log (one log per node)
- ⌘ Group commit

H-Store WAL

Checkpointing

- ⌘ Natural points of consistency
- ⌘ At least once per second
- ⌘ Consistent (not fuzzy)

Frequently Consistent

- ⌘ Low overhead
- ⌘ Uniform overhead
- ⌘ Fast recovery

Requirements

- ⌘ Synchronously copies state
- ⌘ Asynchronously writes to disk
- ⌘ No checkpoint-specific work

Naïve-Snapshot

- ⌘ Maintain untouched copy of every word for duration of checkpoint
- ⌘ Bits determine which copy to use

Wait-Free Zigzag

5	0		1	5		6	1	6	1	5		3	1	6	1	3	
9	0		1	9		9	0		1	9		8	0		1	8	
7	0		1	7		1	1	1	1	7		1	1	1	0		
2	0		1	2		9	1	9	1	2		9	1	9	0		
4	0		1	4		4	0		1	4		4	0		0		
3	0		1	3		3	0		1	3		3	0		0		
AS	Odd	Even	AS	Odd = Current	Even	AS	Odd	Even = Current	AS	Odd	Even = Current	AS	Odd	Even = Current	AS	Odd	Even = Current

(a) At the beginning of time, *AS* and *Even* contain the same information
 (b) During the first checkpoint period, *Odd* collects updates, to the second checkpoint period while *Even* is flushed to disk
 (c) The state right after switching
 (d) In the second checkpoint period, *Odd* and *Even* invert roles

Figure 2: Wait-Free Ping-Pong Example

- ✧ Maintains extra version of app state
- ✧ Swing pointer rather than reset all
- ✧ Cache-friendly interleaved version

Wait-Free Ping-Pong

Uniform overhead

Figure 9: Latency: 1,280K updates/sec

Low overhead
